

## 21 | Equivalences of Categories

Results of Chapters 19 and 20 can be summarized as follows:

**21.1 Theorem.** *Let  $X$  be a connected, locally path connected, and semi-locally simply connected space, and let  $x_0 \in X$ . The map*

$$\Omega: \left( \begin{array}{c} \text{isomorphism classes} \\ \text{of path connected} \\ \text{coverings of } X \end{array} \right) \longrightarrow \left( \begin{array}{c} \text{conjugacy classes} \\ \text{of subgroups} \\ \text{of } \pi_1(X, x_0) \end{array} \right)$$

*given by  $\Omega(p: T \rightarrow X) = p_*(\pi_1(T, \tilde{x}))$  for some  $\tilde{x} \in p^{-1}(x_0)$  is a bijection.*

*Proof.* The map  $\Omega$  is 1-1 by Theorem 19.4, and it is onto by Theorems 20.3 and 20.8. □

Theorem 21.1 translates the topological problem of classifying coverings into an algebraic one, of identifying conjugacy classes of subgroups of a group. However, since coverings over  $X$  form a category  $\mathbf{Cov}(X)$ , with morphisms given by maps of coverings, a more complete correspondence between topology and algebra would be obtained if we could find some algebraic category  $\mathbf{D}$  and a functor

$$F: \mathbf{Cov}(X) \rightarrow \mathbf{D}$$

that would let us restate problems about coverings and maps of coverings as problems about objects and morphism of the category  $\mathbf{D}$ . In Chapter 22 we will show that such category  $\mathbf{D}$  and a functor  $F$  exist. Before we get to this though, we need to consider what properties the functor  $F$  should have so that it would allow us to go back and forth between categories  $\mathbf{Cov}(X)$  and  $\mathbf{D}$  without losing any essential information. The most obvious requirement is that  $F$  should be an isomorphism of categories, i.e. that there should exist a functor  $G: \mathbf{D} \rightarrow \mathbf{Cov}(X)$  such the compositions  $GF: \mathbf{Cov}(X) \rightarrow \mathbf{Cov}(X)$

and  $FG: \mathbf{D} \rightarrow \mathbf{D}$  are identities on all objects and morphisms. It turns out however, that isomorphisms of categories appear very rarely in practical applications. A somewhat weaker but much more useful notion is an equivalence of categories:

**21.2 Definition.** A functor  $F: \mathbf{C} \rightarrow \mathbf{D}$  is an *equivalence of categories* if there exists a functor  $G: \mathbf{D} \rightarrow \mathbf{C}$  for which the following conditions hold:

- 1) For each object  $c \in \mathbf{C}$  there exists an isomorphism  $\eta_c: c \rightarrow GF(c)$  such that for any morphism  $f: c \rightarrow c'$  the following diagram commutes:

$$\begin{array}{ccc} c & \xrightarrow{f} & c' \\ \eta_c \downarrow \cong & & \cong \downarrow \eta_{c'} \\ GF(c) & \xrightarrow{GF(f)} & GF(c') \end{array}$$

- 2) For each object  $d \in \mathbf{D}$  there exists an isomorphism  $\tau_d: d \rightarrow FG(d)$  such that for any morphism  $g: d \rightarrow d'$  the following diagram commutes:

$$\begin{array}{ccc} d & \xrightarrow{g} & d' \\ \tau_d \downarrow \cong & & \cong \downarrow \tau_{d'} \\ FG(d) & \xrightarrow{FG(g)} & FG(d') \end{array}$$

We will say that  $\mathbf{C}$  and  $\mathbf{D}$  are *equivalent categories* if there exists an equivalence  $\mathbf{C} \rightarrow \mathbf{D}$ .

The following fact is often useful, since it allows us to check if a functor is an equivalence of categories without constructing the inverse functor  $G$ .

**21.3 Proposition.** A functor  $F: \mathbf{C} \rightarrow \mathbf{D}$  is an equivalence of categories if and only if the following conditions hold.

- (i) For each object  $d \in \mathbf{D}$  there exists an object  $c \in \mathbf{C}$  such that  $d \cong F(c)$ .
- (ii) For any objects  $c, c' \in \mathbf{C}$  the map  $\text{Mor}_{\mathbf{C}}(c, c') \rightarrow \text{Mor}_{\mathbf{D}}(F(c), F(c'))$  given by  $f \mapsto F(f)$  is a bijection.

*Proof.* Exercise. □

**21.4 Example.** Let  $\mathbf{FVect}(\mathbb{R})$  denote the category of finitely dimensional real vector spaces with linear transformations as morphisms. Also, let  $\mathbf{M}(\mathbb{R})$  denote the category whose objects are natural numbers

$0, 1, 2, \dots$ . The set of morphisms  $\text{Mor}_{\mathbf{M}(\mathbb{R})}(n, m)$  consists of all  $n \times m$  matrices with real coefficients. Composition of morphisms is given by matrix multiplication. We have a functor

$$F: \mathbf{M}(\mathbb{R}) \rightarrow \mathbf{FVect}(\mathbb{R})$$

defined as follows. On objects  $F(n) = \mathbb{R}^n$ . If  $A$  is an  $n \times m$  matrix (i.e. a morphism  $n \rightarrow m$  in  $\mathbf{M}(\mathbb{R})$ ) then  $F(A): \mathbb{R}^n \rightarrow \mathbb{R}^m$  is a linear transformation given by  $F(A)(v) = Av$  for  $v \in \mathbb{R}^n$ . One can show that  $F$  is an equivalence of categories (exercise).

**21.5 Example.** Recall (4.8) that the fundamental groupoid of a space  $X$  is a category  $\Pi_1(X)$  whose objects are points of  $X$ . For  $x, x' \in X$  morphisms  $x \rightarrow x'$  are homotopy classes of paths that begin at  $x$  and end at  $x'$ . Composition of morphisms is given by concatenation of paths. A map of spaces  $f: X \rightarrow X'$  induces a functor of fundamental groupoids  $f_*: \Pi_1(X) \rightarrow \Pi_1(X')$ . One can show that if  $f$  is a homotopy equivalence of spaces then the functor  $f_*$  is an equivalence of categories (exercise).

## Exercises to Chapter 21

E21.1 Exercise. Prove Proposition 21.3.
