

## 20 | From Subgroups to Coverings

In the last chapter we have seen that if  $X$  is a locally path connected space and  $x_0 \in X$  then there are 1-1 functions:

$$\begin{aligned} \left( \begin{array}{c} \text{isomorphism classes} \\ \text{of path connected} \\ \text{coverings of } X \end{array} \right) &\xrightarrow{\Omega} \left( \begin{array}{c} \text{conjugacy classes} \\ \text{of subgroups} \\ \text{of } \pi_1(X, x_0) \end{array} \right) \\ \left( \begin{array}{c} \text{isomorphism classes of} \\ \text{pointed path connected} \\ \text{coverings of } (X, x_0) \end{array} \right) &\xrightarrow{\Omega} \left( \begin{array}{c} \text{subgroups} \\ \text{of} \\ \pi_1(X, x_0) \end{array} \right) \end{aligned}$$

In both cases the function  $\Omega$  associates to a covering  $p: T \rightarrow X$  with  $\tilde{x}_0 \in p^{-1}(x_0)$  the (conjugacy class of) subgroup  $p_*(\pi_1(T, \tilde{x}_0)) \subseteq \pi_1(X, x_0)$ . The natural question is for which subgroups  $H \subseteq \pi_1(X, x_0)$  there exists a covering  $p: T \rightarrow X$  such that  $\Omega(p) = H$ . Our goal here will be to prove that under some assumptions on  $X$  such covering  $p$  exists for any subgroup  $H$ , and so the maps  $\Omega$  given above are bijections. As the first step we will show that  $\Omega$  is a bijection provided that there exists a covering of  $X$  corresponding to the trivial subgroup of  $\pi_1(X, x_0)$ .

**20.1 Definition.** Let  $X$  be a locally path connected space. A *universal covering* of  $X$  is a covering  $\tilde{p}: \tilde{X} \rightarrow X$  such that  $\tilde{X}$  is a simply connected space.

Directly from the Lifting Criterion 19.5 we obtain:

**20.2 Proposition.** Let  $X$  be a locally path connected space and  $\tilde{p}: \tilde{X} \rightarrow X$  be a universal covering of  $X$ . For any covering  $q: T \rightarrow X$  there exists a map of coverings:

$$\begin{array}{ccc}
 \tilde{X} & \xrightarrow{f} & T \\
 & \searrow \tilde{p} & \swarrow q \\
 & X &
 \end{array}$$

Notice that by Exercise 19.2 if  $T$  is path connected then the map  $f$  in Proposition 20.2 is onto. This suggests that if  $X$  has a universal covering then any path connected covering of  $X$  may be obtained as a quotient space of the universal covering space  $\tilde{X}$ . This is the main idea in the proof of the following fact:

**20.3 Theorem.** *Let  $X$  be a locally path connected space and let  $x_0 \in X$ . If there exists a universal covering  $\tilde{p}: \tilde{X} \rightarrow X$  then for each subgroup  $H \subseteq \pi_1(X, x_0)$  there exists a covering  $p_H: T_H \rightarrow X$  and  $\tilde{x}_H \in \tilde{p}^{-1}(x_0)$  such that  $p_{H*}(\pi_1(T_H, \tilde{x}_H)) = H$ .*

*Proof.* Let  $H \subseteq \pi_1(X, x_0)$  be a subgroup. Let  $\tilde{p}: \tilde{X} \rightarrow X$  be a universal covering of  $X$  and let  $y_0 \in \tilde{p}^{-1}(x_0)$ . For each point  $y \in \tilde{X}$  let  $\tau_y$  be a path in  $\tilde{X}$  joining  $y_0$  with  $y$ . Notice that if  $\tilde{p}(y) = \tilde{p}(y')$  then the path  $\tilde{p}\tau_y * \tilde{p}\overline{\tau_{y'}}$  is loop in  $X$  based at  $x_0$ . Notice also that the homotopy class of this loop does not depend on the choice of paths  $\tau_y$  and  $\tau_{y'}$ . Indeed, if  $\sigma_y$  and  $\sigma_{y'}$  are some other paths in  $\tilde{X}$  joining  $y_0$  with, respectively,  $y$  and  $y'$  then, since  $\tilde{X}$  is simply connected, by Proposition 5.6 we obtain  $\tau_y \simeq \sigma_y$  and  $\tau_{y'} \simeq \sigma_{y'}$  which gives a homotopy  $\tilde{p}\tau_y * \tilde{p}\overline{\tau_{y'}} \simeq \tilde{p}\sigma_y * \tilde{p}\overline{\sigma_{y'}}$ .

Define a relation  $\sim$  on  $\tilde{X}$  such that  $y \sim y'$  if

- (i)  $\tilde{p}(y) = \tilde{p}(y')$
- (ii)  $[\tilde{p}\tau_y * \tilde{p}\overline{\tau_{y'}}] \in H$

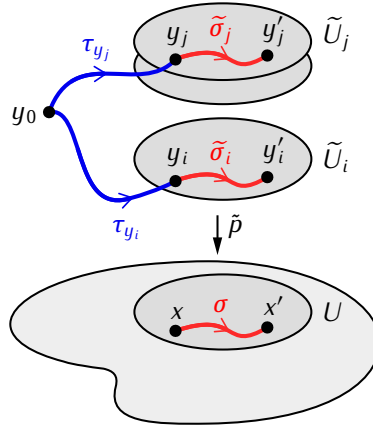

One can check that  $\sim$  is an equivalence relation on  $\tilde{X}$  (exercise). Denote the quotient space by  $X_H$  and let  $q: \tilde{X} \rightarrow X_H$  be the quotient map. We get a commutative diagram

$$\begin{array}{ccc}
 \tilde{X} & \xrightarrow{q} & X_H \\
 & \searrow \tilde{p} & \swarrow p_H \\
 & X &
 \end{array}$$

where  $p_H$  is given by  $p_H([y]) = \tilde{p}(y)$ . We will prove that  $p_H: X_H \rightarrow X$  is a covering. Let  $x \in X$  and let  $U \subseteq X$  be an open neighborhood of  $x$  which is  $U$  is path connected and evenly covered by  $\tilde{p}$ . Such  $U$  exists by the assumption that  $X$  is locally path connected. We will show that  $U$  is evenly covered by  $p_H$ . We have  $\tilde{p}^{-1}(U) = \bigcup_{i \in I} \tilde{U}_i$  where  $\{\tilde{U}_i\}_{i \in I}$  is the set of all distinct slices of  $\tilde{p}$  over  $U$ . Notice that if  $y, y'$  are points in the same slice  $\tilde{U}_i$  and  $y \neq y'$  then  $y \not\sim y'$  since  $\tilde{p}(y) \neq \tilde{p}(y')$ . On the other hand we claim that the following holds:

*Claim.* If  $\tilde{U}_i, \tilde{U}_j$  are two slices, and there exist points  $y_i \in \tilde{U}_i, y_j \in \tilde{U}_j$  such that  $y_i \sim y_j$  then for every  $y'_i \in \tilde{U}_i, y'_j \in \tilde{U}_j$  such that  $\tilde{p}(y'_i) = \tilde{p}(y'_j)$  we have  $y'_i \sim y'_j$ .

To see this denote  $x = \tilde{p}(y_i) = \tilde{p}(y_j)$  and  $x' = \tilde{p}(y'_i) = \tilde{p}(y'_j)$ . Since  $x, x' \in U$  and  $U$  is path connected we can find a path  $\sigma$  in  $U$  such that  $\sigma(0) = x$  and  $\sigma(1) = x'$ . Denote by  $\tilde{\sigma}_i$  and  $\tilde{\sigma}_j$  the lifts of  $\sigma$  to, respectively  $\tilde{U}_i$  and  $\tilde{U}_j$ . Notice that  $\tilde{\sigma}_i(0) = y_i, \tilde{\sigma}_i(1) = y'_i$ , and likewise  $\tilde{\sigma}_j(0) = y_j, \tilde{\sigma}_j(1) = y'_j$ . Denote also by  $\tau_{y_i}, \tau_{y_j}$  paths in  $\tilde{X}$  that connect the point  $y_0$  to, respectively  $y_i$  and  $y_j$ :

By the definition of the relation  $\sim$  in order to show that  $y'_i \sim y'_j$  we only need to verify that  $[\tilde{p}(\tau_{y_i} * \tilde{\sigma}_i) * \tilde{p}(\tau_{y_j} * \tilde{\sigma}_j)] \in H$ . This holds since

$$[\tilde{p}(\tau_{y_i} * \tilde{\sigma}_i) * \tilde{p}(\tau_{y_j} * \tilde{\sigma}_j)] = [\tilde{p}\tau_{y_i} * \sigma * \bar{\sigma} * \tilde{p}\tau_{y_j}] = [\tilde{p}\tau_{y_i} * \tilde{p}\tau_{y_j}]$$

and  $[\tilde{p}\tau_{y_i} * \tilde{p}\tau_{y_j}] \in H$ , since by assumption  $y_i \sim y_j$ .

The statement of the claim implies that for any slice  $\tilde{U}_i$  the set  $q^{-1}(q(\tilde{U}_i))$  is a union of some number of slices of  $\tilde{p}$  over  $U$ , and so it is an open set in  $\tilde{X}$ . This shows that the set  $q(\tilde{U}_i)$  is open in  $X_H$ . It also shows that if  $V \subseteq \tilde{U}_i$  is an open set then  $q(V)$  is open in  $X_H$ . Indeed, it is enough to check that  $q^{-1}(q(V))$  is open in  $\tilde{X}$ , but this holds since  $q^{-1}(q(V)) = \tilde{p}^{-1}(\tilde{p}(V)) \cap q^{-1}(q(\tilde{U}_i))$ .

The claim also implies that we can select a subset  $\{\tilde{U}_{i_k}\}_{k \in K}$  of the set of slices of  $\tilde{p}$  over  $U$  such that the map  $q': \bigcup_{k \in K} \tilde{U}_{i_k} \rightarrow p_H^{-1}(U)$  obtained as a restriction of  $q$  is a continuous bijection. Since by the observation above  $q'$  maps open sets to open sets, the inverse function  $q'^{-1}$  is also continuous, and so  $q'$  is a homeomorphism. Finally, since  $\bigcup_{k \in K} \tilde{U}_{i_k} \cong U \times K$  (where the set  $K$  is taken with the discrete topology) we obtain a homeomorphism  $U \times K \cong p_H^{-1}(U)$ .

Let  $\tilde{x}_H = q(y_0)$ . It remains to prove that  $p_{H*}(\pi_1(T_H, \tilde{x}_H)) = H$ . Let  $\omega$  be a loop in  $X$  based at  $x_0$ , and let  $\tilde{\omega}: [0, 1] \rightarrow X_H$  be the lift of  $\omega$  satisfying  $\tilde{\omega}(0) = \tilde{x}_H$ . Recall that by Theorem 18.1  $[\omega]$  is an element of  $p_{H*}(\pi_1(T_H, \tilde{x}_H))$  if and only if  $\tilde{\omega}$  is a loop in  $X_H$ . Therefore it will suffice to show that  $\tilde{\omega}$  is a loop if and only if  $[\omega] \in H$ . Notice that  $\tilde{\omega} = q\tilde{\omega}'$  where  $\tilde{\omega}': [0, 1] \rightarrow \tilde{X}$  is the lift of  $\omega$  to  $\tilde{X}$  satisfying  $\tilde{\omega}'(0) = y_0$ . From the construction of  $X_H$  it follows that  $\tilde{\omega}$  is a loop if and only if  $\tilde{\omega}'(1) \sim \tilde{\omega}'(0) = y_0$ .

where  $\sim$  is the equivalence relation on  $\tilde{X}$  defined before. Take  $\tilde{\omega}'$  to be a path joining  $y_0$  with  $\tilde{\omega}'(1)$  and take the constant path  $c_{y_0}$  as a path joining  $y_0$  with itself. Using the definition of  $\sim$  we obtain that  $\tilde{\omega}'(1) \sim \tilde{\omega}'(0)$  if and only if  $[\tilde{p}\tilde{\omega}' * \tilde{p}\overline{c_{y_0}}] \in H$ . Since  $[\tilde{p}\tilde{\omega}' * \tilde{p}\overline{c_{y_0}}] = [\omega]$  we obtain that  $\tilde{\omega}'(1) \sim \tilde{\omega}'(0)$  if and only if  $[\omega] \in H$

□

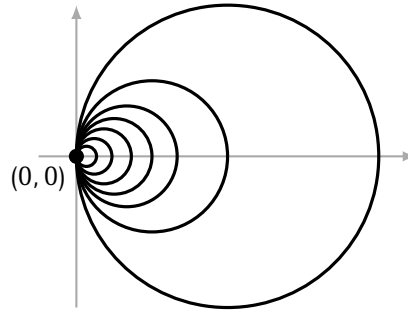

The remaining task is to determine for which spaces a universal covering exists. We will need the following definition:

**20.4 Definition.** A space  $X$  is *semi-locally simply connected* if every point  $x \in X$  has an open neighborhood  $U \subseteq X$  such that the homomorphism  $i_*: \pi_1(U, x) \rightarrow \pi_1(X, x)$  induced by the inclusion map  $i: U \rightarrow X$  is the trivial homomorphism.

Equivalently,  $X$  is semi-locally simply connected if each point in  $X$  has an open neighborhood  $U$  such that any loop based at  $x$  and contained in  $U$  is homotopic to the constant loop, but though a homotopy contained in  $X$  (and not necessarily a homotopy contained in  $U$ ).

**20.5 Example.** If  $X$  is a space such that each point  $x \in X$  has an open neighborhood  $U$  where  $\pi_1(U, x)$  is the trivial group, then  $X$  is semi-locally simply connected. One can use this to show, for example, that every topological manifold is semi-locally simply connected. On the other hand, it is possible to find a semi-locally simply connected space  $X$ , such that for some point  $x \in X$  every open neighborhood of  $x$  has a non-trivial fundamental group.

**20.6 Example.** The *Hawaiian earring* space is a subspace  $X \subseteq \mathbb{R}^2$  given by  $X = \bigcup_{n=1}^{\infty} C_n$  where  $C_n$  is the circle with radius  $\frac{1}{n}$  and center at the point  $(0, \frac{1}{n})$ :

This space is not semi-locally simply connected since for each open neighborhood  $U$  of the point  $x_0 = (0, 0)$  the homomorphism  $\pi_1(U, x_0) \rightarrow \pi_1(X, x_0)$  is non-trivial.

Semi-local simple connectedness is a necessary condition for existence of a universal covering:

**20.7 Proposition.** *If  $X$  is space such that there exists a universal covering  $p: \tilde{X} \rightarrow X$  then  $X$  is semi-locally simply connected.*

*Proof.* Exercise. □

Conversely, we will show that the following holds:

**20.8 Theorem.** *If  $X$  is a space which is connected, locally path connected, and semi-locally simply connected then there exists a universal covering  $p: \tilde{X} \rightarrow X$ .*

*Proof.* Let  $X$  be a space satisfying assumptions of the theorem. We will say that an open set  $U \subseteq X$  is *trivial* if  $U$  is path connected and for any  $x \in U$  the homomorphism  $i_*: \pi_1(U, x) \rightarrow \pi_1(X, x)$  induced by the inclusion map  $i: U \rightarrow X$  is trivial. Since  $X$  is locally path connected and semi-locally simply connected trivial sets form a basis of the topology on  $X$ , that is any open set in  $X$  is a union of trivial sets.

The first step in the construction of a universal covering  $p: \tilde{X} \rightarrow X$  is to describe the set of points of the space  $\tilde{X}$ . This description will be based on the following reasoning. Assume that we already have a universal covering  $p: \tilde{X} \rightarrow X$ , let  $x_0 \in X$  and let  $\tilde{x}_0 \in p^{-1}(x_0)$ . Since the space  $\tilde{X}$  is path connected, for any point  $\tilde{x} \in \tilde{X}$  there exists a path  $\tilde{\omega}$  such that  $\tilde{\omega}(0) = \tilde{x}_0$  and  $\tilde{\omega}(1) = \tilde{x}$ . Moreover, since  $\tilde{X}$  is simply connected any two such path in  $\tilde{X}$  are homotopic. In effect the assignment  $[\tilde{\omega}] \mapsto \tilde{\omega}(1)$  gives a bijection:

$$\left( \begin{array}{l} \text{homotopy classes of paths} \\ \tilde{\omega}: [0, 1] \rightarrow \tilde{X} \\ \text{with } \tilde{\omega}(0) = \tilde{x}_0 \end{array} \right) \cong \left( \begin{array}{l} \text{points of } \tilde{X} \end{array} \right)$$

Notice that we also have a bijection:

$$\left( \begin{array}{l} \text{homotopy classes of paths} \\ \tilde{\omega}: [0, 1] \rightarrow \tilde{X} \\ \text{with } \tilde{\omega}(0) = \tilde{x}_0 \end{array} \right) \cong \left( \begin{array}{l} \text{homotopy classes of paths} \\ \omega: [0, 1] \rightarrow X \\ \text{with } \omega(0) = x_0 \end{array} \right)$$

which assigns to the homotopy class of a path  $\tilde{\omega}$  in  $\tilde{X}$  the homotopy class of  $p\tilde{\omega}$ . The inverse function sends the homotopy class of a path  $\omega$  in  $X$  to the homotopy class of  $\tilde{\omega}$ , where  $\tilde{\omega}$  is the unique lift of  $\omega$  satisfying  $\tilde{\omega}(0) = \tilde{x}_0$ .

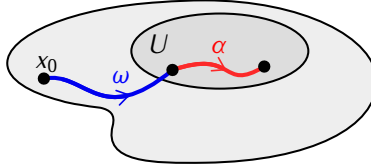

In effect we get a bijective correspondence:

$$\left( \begin{array}{l} \text{points of } \tilde{X} \end{array} \right) \cong \left( \begin{array}{l} \text{homotopy classes of paths} \\ \omega: [0, 1] \rightarrow X \\ \text{with } \omega(0) = x_0 \end{array} \right)$$

The upshot of this argument is that if we are given a space  $X$  then we can define  $\tilde{X}$  to be the set on the right hand side of the above bijection.

Next, we need to define a topology on the set  $\tilde{X}$ . Let  $[\omega] \in \tilde{X}$ , and let  $U$  be a trivial set such that  $\omega(1) \in U$ . Define:

$$U[\omega] = \{[\omega * \alpha] \mid \alpha: [0, 1] \rightarrow U, \alpha(0) = \omega(1)\}$$

One can check that the collection of all sets  $U[\omega]$  defined in this way is a basis of a topology on  $\tilde{X}$  (exercise). We will consider  $\tilde{X}$  as a topological space with topology defined by this basis.

Consider the function  $p: \tilde{X} \rightarrow X$  given by  $p([\omega]) = \omega(1)$ . We will show that this is a universal covering of  $X$ . We will use the following observations, proofs of which are left as an exercise:

(i) For any trivial set  $U \subseteq X$  and any path  $[\omega] \in \tilde{X}$  such that  $\omega(1) \in U$  the map

$$p|_{U[\omega]}: U[\omega] \rightarrow U$$

is a homeomorphism.

(ii) Let  $U \subseteq X$  be a trivial set, let  $x \in U$  and let  $H(x_0, x) = \{[\omega] \in \tilde{X} \mid \omega(1) = x\}$ . Then

$$p^{-1}(U) = \bigcup_{[\omega] \in H(x_0, x)} U[\omega]$$

Moreover  $U[\omega] \cap U[\omega'] = \emptyset$  for all  $[\omega], [\omega'] \in H(x_0, x)$ ,  $[\omega] \neq [\omega']$ .

(iii) For a path  $\omega: [0, 1] \rightarrow X$  such that  $\omega(0) = x_0$  and for  $s \in [0, 1]$  let  $\omega_s$  be the path in  $X$  defined by  $\omega_s(t) = \omega(st)$ . The function  $h_\omega: [0, 1] \rightarrow \tilde{X}$  given by  $h_\omega(s) = [\omega_s]$  is continuous.

Directly from (ii) it follows that the function  $p$  is continuous. Furthermore, combining (ii) and (i) we obtain that  $p$  is covering and that each trivial set in  $X$  is evenly covered by  $p$ .

Next, by (iii) the space  $\tilde{X}$  is path connected. Indeed, for any  $[\omega] \in \tilde{X}$  the function  $h_\omega$  is a path in  $\tilde{X}$  joining  $[\omega]$  with  $[c_{x_0}]$ , the homotopy class of the constant path at  $x_0$ . It remains then to show that the fundamental group  $\pi_1(\tilde{X}, [c_{x_0}])$  is trivial, or equivalently that  $p_*(\pi_1(\tilde{X}, [c_{x_0}]))$  is the trivial subgroup of  $\pi_1(X, x_0)$ . Assume then that  $\omega$  is a loop in  $X$  such that  $[\omega] \in p_*(\pi_1(\tilde{X}, [c_{x_0}]))$ . By Theorem 18.1 this means that the lift of  $\omega$  to  $\tilde{X}$  that starts at  $[c_{x_0}]$  is a loop in  $\tilde{X}$ . Notice, however, that this lift is given the path  $h_s$  defined in (iii). This path is a loop only when  $[c_{x_0}] = h_\omega(0) = h_\omega(1) = [\omega]$  i.e. only when  $[\omega]$  is the trivial element of  $\pi_1(X, x_0)$ .

□

### Exercises to Chapter 20

E20.1 Exercise. Prove Proposition 20.7.

E20.2 Exercise. Let  $X, Y$  be connected and locally path connected spaces, and let  $\tilde{p}_X: \tilde{X} \rightarrow X$ , and  $\tilde{p}_Y: \tilde{Y} \rightarrow Y$  be their universal coverings. Show that if  $X \simeq Y$  then  $\tilde{X} \simeq \tilde{Y}$ .

E20.3 Exercise. Describe explicitly all non-isomorphic coverings of the space  $\mathbb{R}P^2 \times \mathbb{R}P^2$

E20.4 Exercise. Let  $X$  be a space, and let  $A \subseteq X$ . Assume that both  $X$  and  $A$  are connected and locally path connected, and that the inclusion map  $i: A \rightarrow X$  induces an isomorphism of the fundamental groups

$$i_*: \pi_1(A, x_0) \xrightarrow{\cong} \pi_1(X, x_0)$$

for  $x_0 \in A$ . Show that if  $\tilde{p}: \tilde{X} \rightarrow X$  is a universal covering of  $X$  then the map  $\tilde{p}|_{\tilde{p}^{-1}(A)}: \tilde{p}^{-1}(A) \rightarrow A$  is a universal covering of  $A$ .

E20.5 Exercise. a) Let  $X$  be a finite, path connected, 1-dimensional CW complex. Show that if  $\tilde{p}: \tilde{X} \rightarrow X$  is the universal covering of  $X$  then the space  $\tilde{X}$  has the structure of a 1-dimensional CW complex such that  $\tilde{p}$  is a cellular map.

b) Use part a) to show that if  $F$  is a finitely generated free group then every subgroup of  $F$  is free.

c) Recall that  $[G : H]$  denotes the index of a subgroup  $H$  in a group  $G$ . Let  $F$  be free group on  $n$  generators, and let  $H$  be a subgroup of  $F$ . Show that if  $[F : H] = k$  then  $H$  is a free group on  $(n - 1)k + 1$  generators.
